

Name: Kaleb Alstott
Assignment 2

Mitigation: I would implement an input field validation as well as parametrized URL's and queries. The reason on why I chose for a validation input field is for the purpose of making sure what is entered by the user is acceptable and if it were not an error message would arise. This would ensure that users are using the input fields correctly and safely. As for parameterized URL's and queries this would help to ensure that SQL injections are protected against due to the restraints set up. This would simply provide parameters in the SQL queries and URL, then connect values to those parameters, and then execute the query. By doing so we can separate out SQL code from user input and protect against SQL injections.
